by parenteral supplementation through a central vein can be an effective method of supplying nutrients to patients with depleted nutritional status who are required to exercise. During exercise there can be negative consequences for the patient if the nutritional support system breaks down. A case of a patient with bowel obstruction who required restorative surgery after a laparotomy was given

enteral nutrition by jejunal tube for 7 days. The patient then began exercise on the treadmill which caused the tube to be displaced from the jejunal loop. The patient then developed vomiting of the undigested enteral formula. By 2 days after the initial feeding tube insertion the patient was completely fed by the enteral route. The tube was reinserted and nutrition continued for an additional 2 weeks. The

patient responded appropriately to exercise. This paper documents a case in which the use of enteral nutrition in the acute phase following major abdominal surgery provided an effective nutritional support system for an exercise-dependent patient. This paper identifies the risks of early tube removal from a patient in the acute phase following an operation.Q: SpaceInvaders60, Snakeminer/Magminer/Crunchmi
